5           THIS IS A CONTINUATION-IN-PART OF APPLICATION  
              SERIAL NO. 07/753,216 FILED AUGUST 30, 1991

**BACKGROUND OF THE INVENTION**

10          1.    Field of The Invention

              The present invention relates to a slurry which  
              undergoes exothermic reaction by combustion synthesis  
              when ignited, and methods for the use thereof in joining  
              metallic or ceramic surfaces or for coating metallic,  
15           ceramic and refractory surfaces. Although not so  
              limited, slurries of the invention have particular  
              utility in joining stainless steel, aluminum, carbon  
              steel and copper workpieces and in forming coatings on  
              porous silica or aluminum oxide substrates which resist  
20           chemical attack, ingress and attack by molten alloys  
              having high melting temperatures.

              2.   Prior Art

              Joints between metal pieces are conventionally  
25           formed by welding or brazing, by means of a wide variety  
              of techniques using an oxyacetylene torch, or the like.  
              Brazing compositions for joining metal pieces by fusion  
              are also well known. To the best of applicant's  
              knowledge there have been no suggestions in the prior art  
30           to use a slurry for joining metallic pieces, the  
              constituents of which are so selected and proportioned as  
              to undergo exothermic reaction by combustion synthesis  
              when ignited, thereby welding the metal pieces together.

              Ceramic materials such as silica, alumina,  
35

1        zirconia and the like are used for containing  
molten metals, in furnaces for melting metals, in  
armor for missiles and the like, as infrared  
sensors, in electronic packaging, in engine  
5        materials, and in related applications. Such  
ceramic materials are frequently porous because  
they are made from powders which are sintered.  
Although porosity may be beneficial in imparting  
low density and specific toughness, porosity is  
10       detrimental from the standpoint of chemical attack,  
ingress into the ceramic or refractory material and  
resistance against attack by molten alloys at high  
temperature. Expensive fabrication is necessary to  
obtain a ceramic material of the above type in a  
15       fully densified condition. The prior art has  
resorted to coating ceramic surfaces in order to  
eliminate ingress or diffusion of material such as  
molten metal into the ceramic. No generally  
suitable technique is known to applicant to solve  
20       the problems inherent in coating ceramic or  
refractory surfaces.

      Despite the existence of a wide variety of  
welding and brazing techniques and compositions,  
25       and despite the prior art suggestions for coating  
porous ceramic or refractory surfaces, a genuine  
need exists for alternative compositions and  
methods for joining metallic or ceramic surfaces or  
for coating metallic, ceramic and refractory  
30       surfaces.

#### SUMMARY OF THE INVENTION

      It is an object of the invention to provide a  
35       slurry for joining metallic or ceramic surfaces or

1 for coating metallic, ceramic and refractory  
surfaces, by the use of constituents which undergo  
exothermic reaction by combustion synthesis.

5 It is a further object of the invention to  
provide methods for joining metal or ceramic  
surfaces and for coating metallic, ceramic and  
refractory surfaces by means of slurries which  
undergo exothermic reaction by combustion synthesis.

10 According to the invention there is provided a  
slurry for joining metallic or ceramic surfaces or  
for coating metallic or ceramic and refractory  
surfaces, the slurry comprising a liquid suspending  
15 medium and at least two constituents suspended in  
particulate form in the medium and selected from  
the group consisting of titanium dioxide, boron  
oxide, aluminum oxide, aluminum, silicon, titanium,  
boron, nickel, phosphorus, chromic oxide, carbon,  
20 niobium, zirconium, tantalum, molybdenum, hafnium,  
and vanadium, the constituents being so selected  
and proportioned as to undergo exothermic reaction  
by combustion synthesis when ignited.

25 Liquid suspending mediums are monoaluminum  
phosphate, colloidal silica, methyl cellulose,  
alcohols, acetone, water, sodium silicate, and  
combinations of common acids and bases.

30 Optionally, the slurry may also contain  
diluent or reinforcing agents, which do not  
undergo combustion synthesis, in particulate form,  
including but not limited to metals such as  
aluminum, iron, copper and silver, and  
35 non-metallics such as borides, carbides, nitrides,

1       oxides and silicides of titanium, niobium, and  
chromium.

5       A slurry for coating metallic or ceramic and  
refractory surfaces, in accordance with the  
invention, comprises a liquid suspending medium and  
particulate constituents suspended in the medium  
capable of undergoing exothermic reaction by  
combustion synthesis when ignited, the constituents  
10       being selected from the group consisting of  
titanium and crystalline carbon; titanium and  
amorphous carbon; titanium and aluminum; aluminum,  
titanium dioxide, and boron oxide; aluminum oxide,  
titanium, and amorphous carbon; and mixtures  
15       thereof.

20       A slurry for joining metallic or ceramic  
surfaces, in accordance with the invention,  
comprises a liquid suspending medium and  
particulate constituents suspended in the medium  
capable of undergoing exothermic reaction by  
combustion synthesis when ignited, the constituents  
being selected from the group consisting of  
titanium dioxide, boron oxide, aluminum, titanium,  
25       boron, nickel and phosphorus; titanium and boron;  
titanium, boron, nickel and phosphorus; chromic  
oxide, carbon and aluminum; and mixtures thereof.

30       A method of coating metallic or ceramic and  
refractory surfaces in accordance with the  
invention comprises the steps of providing a slurry  
having a liquid suspending medium and particulate  
constituents suspended in the medium capable of  
undergoing exothermic reaction by combustion  
35       synthesis when ignited, the constituents being

1 selected from the group consisting of titanium and  
crystalline carbon; titanium and amorphous carbon;  
titanium and aluminum; aluminum, titanium dioxide  
and boron oxide; aluminum oxide, titanium, and  
5 amorphous carbon; and mixtures thereof; applying  
the slurry to a metallic, ceramic or refractory  
surface so as to form a layer of uniform thickness  
thereon; and igniting the layer to cause combustion  
synthesis thereof; thereby forming an adherent  
10 coating of titanium carbide; titanium aluminide; a  
titanium boride and aluminum oxide composite; or an  
aluminum oxide, titanium dioxide and titanium  
carbide composite .

15 The invention further provides a method of  
joining metallic or ceramic surfaces, which  
comprises the steps of providing a slurry having a  
liquid suspending medium and particulate  
constituents suspended in the medium capable of  
20 undergoing exothermic reaction by combustion  
synthesis when ignited, the constituents being  
selected from the group consisting of titanium  
dioxide, boron oxide, aluminum, titanium, boron,  
nickel and phosphorus; titanium and boron;  
25 titanium, boron, nickel and phosphorus; chromic  
oxide, carbon and aluminum; and mixtures thereof;  
applying the slurry to metallic or ceramic surfaces  
to be joined, placing the metallic or ceramic  
surfaces in abutting relation with the applied  
30 slurry therebetween; and igniting the slurry to  
cause combustion synthesis thereof at a temperature  
sufficient to fuse the metallic or ceramic surfaces  
together.

35

1

DETAILED DESCRIPTION OF THE INVENTION

5 In the embodiment of the invention adapted for coating ceramic and refractory surfaces, preferred particulate constituents comprise, in weight percent based on the total weight of constituents, the following groups:

10 from 75% to 85% titanium, and 15% to 25% crystalline carbon;

from 75% to 85% titanium, and 15% to 25% amorphous carbon;

15 from 60% to 68% titanium, and 32% to 40% aluminum;

20 from 35% to 41% aluminum, 30% to 36% titanium dioxide, and 27% to 31% boron oxide;

from 50% to 97.5% aluminum oxide, 2% to 25% titanium, and 0.5% to 25% amorphous carbon.

25 A preferred liquid suspending medium for the slurry is monoaluminum phosphate and/or colloidal silica. Both these liquids are reactive with the reactants, which is desirable since they become an integral part of the final coating.

30 Water and acetone were also tested as liquid suspending mediums and found to be unsatisfactory since the low evaporation temperatures thereof resulted in cracks and distortion in the coatings during drying.

35

1 In the embodiment of a slurry adapted for  
joining metallic surfaces, preferred particulate  
constituents comprise, in weight percent based on  
the total weight of the constituents, the following  
5 groups:

from 28% to 32% titanium dioxide, 25% to  
27% boron oxide, 32% to 35% aluminum, 3% to 4%  
titanium, 1.5% to 2.0% boron, 3.8% to 4.5% nickel,  
10 and 0.7% to 1.1% phosphorous;

from 60% to 70% titanium, and 30% to 40%  
boron;

15 from 30% to 35% titanium, 15% to 20%  
boron, 38% to 44% nickel, and 8% to 10% phosphorus;

from 12% to 20% titanium dioxide, 10% to  
16% boron oxide, 15% to 20% aluminum, 0 to 10%  
20 iron, 15% to 17.5% titanium, 8% to 9.5% boron, 19%  
to 22% nickel, and 4% to 5% phosphorus;

from 67% to 70% chromic oxide, 6.5% to 8%  
carbon, and 23% to 26% aluminum.

25

All constituents should have an average  
particle size of less than 53 microns (i.e.,  
passing 270 mesh screen). Materials are generally  
available having average particle sizes of -300 or  
30 -325 mesh screen.

The amount of liquid suspending medium is not  
critical and is selected to provide a viscosity  
suitable to permit application by painting,  
35 spraying or dipping, while at the same time

1 avoiding excessive run-off. When coating metallic  
or ceramic or refractory surfaces, it is preferred  
to form a layer of slurry having a thickness of  
about 0.2 to 0.3 mm. In general, from about 1 to  
5 about 12 parts by weight of the powdered  
constituents are dispersed uniformly in from about  
2 to about 5 parts by volume of the liquid  
suspending medium, although these limits can be  
varied depending upon the particular mixture of  
10 constituents.

Tests have been conducted on slurries for  
coating ceramic surfaces. For test purposes five  
examples of powdered constituents were prepared as  
15 follows:

Example 1 - titanium 80%, crystalline carbon 20%

20 Example 2 - titanium 80%, amorphous carbon 20%

Example 3 - titanium 64%, aluminum 36%

Example 4 - titanium dioxide 33%, boron oxide 29%,  
aluminum 38%.

25 Example 5 - aluminum oxide 95-97.5%, titanium 2-4%,  
amorphous carbon 0.5-1%.

The percentages above are by weight. The  
30 titanium, carbon, and aluminum powders were  
obtained from ALFA or from Johnson Matthey Electric  
and ranged in purity from 99.0% to 99.5%. The  
crystalline and amorphous carbon powders were -300  
mesh particle size, while the titanium and aluminum  
35 powders were -325 mesh. Titanium dioxide and boron

1 oxide were obtained from Fisher, grade designations  
LO-904811 and LO-904641, respectively. Aluminum  
oxide was obtained from Alcoa Chemicals, grade  
5 designation A-17. Slurries were prepared by mixing  
uniformly 1 part by weight of the powders of the  
above examples with 2 parts by volume of each of  
four different liquid suspension media, viz.,  
water, colloidal silica, monoaluminum phosphate and  
acetone, for Examples 1-4. As indicated above,  
10 preliminary tests indicated that water and acetone  
were unsuitable, and hence were not subjected to  
further tests. Monoaluminum phosphate (MAP) was  
found to be the preferred suspension medium.

15 For Example 5, the liquid suspension media were  
MAP 90% and colloidal silica 10% by volume, and MAP  
95% and colloidal silica 5% by volume. The  
colloidal silica was REMET-SP30. Slurries were  
prepared by mixing uniformly 1 part by weight of  
20 the powder with 1.5 part by volume of suspension  
medium.

Fused silica substrates were coated by painting  
to form a layer of 0.25 mm (250 microns) thickness  
25 with slurries of each of the above examples 1-4 in  
MAP. After coating, reaction was initiated either  
by a wave propagation mode or thermal explosion  
mode of reaction in air.

30 In the wave propagation mode, reaction was  
started from one part of the sample with a butane  
flame torch, and the reaction then self-propagated  
across the sample. Since each of examples 1-4 had  
a different heat of reaction, it was necessary to  
35 heat samples to different initial temperatures to

1 sustain the combustion synthesis.

5 In the thermal explosion mode reaction was started simultaneously in all parts of the sample subsequent to a heating and drying step. Samples of Examples 1-4 were heated from room temperature to 1000° C and then cooled slowly in a furnace to avoid possible surface cracks in the coatings. The thermal explosion mode in air is the preferred  
10 method.

Examples 1-4 reacted by combustion synthesis as follows:

- 15 1. Ti+C (crystalline) - TiC  
2. Ti+C (amorphous) - TiC  
3. Ti+Al - TiAl  
4.  $10/3 \text{ Al} + \text{TiO}_2 + \text{B}_2\text{O}_3 - \text{TiB}_2 + 5/3 \text{ Al}_2\text{O}_3$

20 The surfaces resulting from reactions 1 and 2 above had lower porosity than those produced by reactions 3 and 4.

25 Fused silica specimens coated with titanium carbide (Examples 1 and 2) were immersed in molten aluminum at 700° C and kept in the melting furnace for 7 days. For comparison uncoated fused silica specimens were also subjected to the same test. At the end of 7 days, samples were cut along their  
30 cross-sections and tested. In the ceramic specimens coated with titanium carbide, diffusion of aluminum into the ceramic body was not observed. In contrast to this, aluminum penetration to a depth of 0.5 mm occurred in the uncoated specimens.

35

1       The slurry of Example 5 was applied by dipping  
silica crucibles two or three times at 5 second  
intervals to obtain a coating thickness of 150-200  
microns. After coating, samples were dried for 10  
5       hours. The coated crucibles were then placed in a  
furnace which reached 1200° C in 2 hours and held at  
that temperature for 4 hours. The resulting  
combustion synthesis reaction (by thermal explosion  
mode in air) was as follows:

10

Molten stainless steel was then poured into the  
coated silica crucibles. It was found that these  
15       crucibles could be reused for several heats of molten  
stainless steel. By way of comparison, an uncoated  
silica crucible could be used for only one heat due  
to extensive surface damage.

20       Numerous tests have been conducted on slurries of  
the invention for use in joining metallic surfaces.  
The following test procedures were used:

A - Samples in the form of rods (0.54 cm  
25       diameter, 5 cm length) were clamped in a Gleeble  
machine with the combustible slurry between the rod  
ends, using various joint geometries. (The Gleeble  
is a standard thermomechanical apparatus which  
applies both stress and temperature to a sample.)  
30       Current was then passed through each sample until the  
mixture reached ignition temperature and underwent  
combustion.

B - Bars of various sizes were butted together  
35       with a slurry in MAP between them. Another

1 combustible slurry was spread around the joint and  
ignited using an oxyacetylene torch. After  
combustion the slurry outside the joint was then  
chipped off.

5

C - Bars of various sizes were butted together,  
using a butt joint, with a slurry between the  
abutting ends and ignited by an oxyacetylene torch.

10

D - Mild steel bars of various thicknesses were  
joined using a silver brazing alloy foil in the joint  
and a combustibile slurry around the outside of the  
joint.

15

The compositions, in weight percent, of the  
powdered constituents were as follows:

Example 6 - titanium dioxide 30%, boron oxide 26.25%,  
aluminum 33.75%, titanium 3.25%, boron 1.75%, nickel  
20 4.1%, phosphorus 0.9%;

Example 7 - titanium 65%, boron 35%;

Example 8 - titanium 32.5%, boron 17.5%, nickel 41%,  
25 phosphorus 9%;

Example 9 - titanium dioxide 16.67%, boron oxide  
14.58%, aluminum 18.75%, titanium 16.25%, boron  
8.75%, nickel 20.5%, phosphorus 4.5%;

30

Example 10 - chromic oxide 68.5%, carbon 7.2%,  
aluminum 24.3%.

Slurries were prepared of all the above examples  
35 in MAP by mixing 1 gram of the powder with 0.3 cc of

1       MAP. Maximum reaction temperatures were determined  
in preliminary tests, and it was found that the  
highest reaction temperature was achieved by Example  
6. This composition was therefore used in further  
5       tests.

Test data on the four procedures by which rods or  
bars were joined are tabulated below. While results  
were not uniformly successful with the slurries of  
10       the invention, comparison of joints prepared by  
procedure D with a conventional fusion welded joint  
using an oxyacetylene torch indicated that joint  
strength when using an optimum amount of slurry was  
generally comparable with joint strength obtained by  
15       conventional welding. In this connection the joint  
thickness was found to have a marked effect on joint  
strengths both for procedure D and conventional  
fusion welded joints, as shown in Table 5.

SUBSTITUTE SHEET

1     CLAIMS:

5           1.    A slurry for joining metallic or ceramic  
surfaces or for coating metallic or ceramic and  
refractory surfaces, said slurry comprising a  
liquid suspending medium and at least two  
constituents suspended in particulate form in said  
medium and selected from the group consisting of  
titanium dioxide, boron oxide, aluminum oxide,  
10   aluminum, silicon, titanium, boron, nickel,  
phosphorus, chromic oxide, carbon, niobium,  
zirconium, tantalum, molybdenum, hafnium, and  
vanadium, said constituents being so selected and  
proportioned as to undergo exothermic reaction by  
15   combustion synthesis when ignited.

          2.    The slurry of claim 1, wherein said liquid  
suspending medium is monoaluminum phosphate or  
colloidal silica.

20           3.    The slurry of claim 1, wherein said  
constituents comprise, in weight percent, from 28%  
to 32% titanium dioxide, 25% to 27% boron oxide,  
32% to 35% aluminum, 3% to 4% titanium, 1.5% to  
25   2.0% boron, 3.8% to 4.5% nickel, and 0.7% to 1.1%  
phosphorus.

          4.    The slurry of claim 1, wherein said  
constituents comprise, in weight percent, from 60%  
30   to 70% titanium, and 30% to 40% boron.

          5.    The slurry of claim 1, wherein said  
constituents comprise, in weight percent, from 30%  
to 35% titanium, 15% to 20% boron, 38% to 44%  
35   nickel, and 8% to 10% phosphorus.

1           6.    The slurry of claim 1, wherein said  
              constituents comprise, in weight percent, from 12%  
              to 20% titanium dioxide, 10% to 16% boron oxide,  
              15% to 20% aluminum, 0% to 10% iron, 15% to 17.5%  
5           titanium, 8% to 9.5% boron, 19% to 22% nickel, and  
              4% to 5% phosphorus.

              7.    The slurry of claim 1, wherein said  
              constituents comprise, in weight percent, from 67%  
10           to 70% chromic oxide, 6.5% to 8% carbon, and 23% to  
              26% aluminum.

              8.    The slurry of claim 1, wherein said  
              constituents comprise, in weight percent, from 75%  
15           to 85% titanium, and 15% to 25% crystalline carbon.

              9.    The slurry of claim 1, wherein said  
              constituents comprise, in weight percent, from 75%  
              to 85% titanium, and 15% to 25% amorphous carbon.

20           10.   The slurry of claim 1, wherein said  
              constituents comprise, in weight percent, from 50%  
              to 97.5% aluminum oxide; 2% to 25% titanium, and  
              0.5% to 25% amorphous carbon.

25           11.   The slurry of claim 1, wherein said  
              constituents comprise, in weight percent, from 60%  
              to 68% titanium, and 32% to 40% aluminum.

30           12.   The slurry of claim 1, wherein said  
              constituents comprise, in weight percent, from 30%  
              to 36% titanium dioxide, 27% to 31% boron oxide,  
              and 35% to 41% aluminum.

35           13.   The slurry of claim 1, wherein said

1 constituents have an average particle size of less  
than 53 microns (-270 mesh screen).

5 14. The slurry of claim 1, including  
particulate diluents selected from the group  
consisting of aluminum, iron, copper, silver,  
borides, carbides, nitrides, and silicides of  
titanium, niobium, and chromium, and mixtures  
thereof.

10 15. The slurry of claim 2, wherein from about  
8 to about 12 parts by weight of said constituents  
in particulate form are dispersed uniformly in  
about 2 to about 5 parts by volume of said liquid  
15 suspending medium.

20 16. A slurry for coating metallic or ceramic  
and refractory surfaces, comprising a liquid  
suspending medium and particulate constituents  
suspended in said medium capable of undergoing  
exothermic reaction by combustion synthesis when  
ignited, said constituents being selected from the  
group consisting of titanium and crystalline  
carbon; titanium and amorphous carbon; titanium  
25 and aluminum; aluminum, titanium dioxide, and boron  
oxide; aluminum oxide, titanium, and amorphous  
carbon; and mixtures thereof.

30 17. The slurry of claim 16, wherein said  
liquid suspending medium is monoaluminum phosphate  
and/or colloidal silica.

35 18. The slurry of claim 16, wherein said  
constituents comprise, in weight percent, from 75%  
to 85% titanium, and 15% to 25% crystalline or

1 amorphous carbon.

19. The slurry of claim 16, wherein said  
constituents comprise, in weight percent, from 50%  
5 to 97.5% aluminum oxide, 2% to 25% titanium, and  
0.5% to 25% amorphous carbon.

20. The slurry of claim 16, wherein said  
constituents comprise, in weight percent, from 60%  
10 to 68% titanium, and 32% to 40% aluminum.

21. The slurry of claim 16, wherein said  
constituents comprise, in weight percent, from 35%  
to 41% aluminum, 30% to 36% titanium dioxide, and  
15 27% to 31% boron oxide.

22. The slurry of claim 16, wherein said  
constituents have an average particle size of less  
than 53 microns (-270 mesh screen).

20 23. The slurry of claim 18, wherein the  
average particle size of titanium is greater than  
that of crystalline carbon.

24. The slurry of claim 17, wherein about 1  
25 part by weight of said constituents in particulate  
form is dispersed uniformly in about 1 to 2 parts  
by volume of said liquid suspending medium.

25. A slurry for joining metallic or ceramic  
30 surfaces, comprising a liquid suspending medium and  
particulate constituents suspended in said medium  
capable of undergoing exothermic reaction by  
combustion synthesis when ignited, said  
35 constituents being selected from the group

1 consisting of titanium dioxide, boron oxide,  
aluminum, titanium, boron, nickel and phosphorus;  
titanium and boron; titanium, boron, nickel and  
phosphorus; chromic oxide, carbon and aluminum; and  
5 mixtures thereof.

26. The slurry of claim 25, wherein said  
liquid suspending medium is monoaluminum phosphate  
or colloidal silica.

10 27. The slurry of claim 25, wherein said  
constituents comprise, in weight percent, from 28%  
to 32% titanium dioxide, 25% to 27% boron oxide,  
32% to 35% aluminum, 3% to 4% titanium, 1.5% to  
15 2.0% boron, 3.8% to 4.5% nickel, and 0.7% to 1.1%  
phosphorus.

28. The slurry of claim 25, wherein said  
constituents comprise, in weight percent, from 60%  
20 to 70% titanium, and 30% to 40% boron.

29. The slurry of claim 25, wherein said  
constituents comprise, in weight percent, from 30%  
to 35% titanium, 15% to 20% boron, 38% to 44%  
25 nickel, and 8% to 10% phosphorus.

30. The slurry of claim 25, wherein said  
constituents comprise, in weight percent, from 15%  
to 20% titanium dioxide, 13% to 16% boron oxide,  
30 17% to 20% aluminum, 15% to 17.5% titanium, 8% to  
9.5% boron, 19% to 22% nickel, and 4% to 5%  
phosphorus.

31. The slurry of claim 25, wherein said  
35 constituents comprise, in weight percent, from 67%

1 to 70% chromic oxide, 6.5% to 8% carbon, and 23% to  
26% aluminum.

5 32. The slurry of claim 25, wherein said  
constituents have an average particle size of less  
than 53 microns (-270 mesh screen).

10 33. A method of coating metallic or ceramic  
and refractory surfaces whereby to provide  
chemically resistant coatings having decreased  
porosity, said method comprising the steps of  
providing a slurry having a liquid suspending  
medium and particulate constituents suspended in  
said medium capable of undergoing exothermic  
15 reaction by combustion synthesis when ignited, said  
constituents being selected from the group  
consisting of titanium and crystalline carbon;  
titanium and amorphous carbon; titanium and  
aluminum; aluminum, titanium dioxide, and boron  
20 oxide; aluminum oxide, titanium and amorphous  
carbon; and mixtures thereof; applying said slurry  
to a metallic, ceramic or refractory surface so as  
to form a layer of uniform thickness thereon; and  
igniting said layer to cause combustion synthesis  
25 thereof; thereby forming an adherent coating of  
titanium carbide; titanium aluminide; or a titanium  
boride and aluminum oxide composite.

30 34. The method of claim 33, wherein said step  
of igniting said layer comprises a wave propagation  
mode or a thermal explosion mode of reaction in air.

35 35. The method of claim 33, wherein said step  
of applying said slurry comprises painting,  
spraying or dipping to form a layer having a

1 thickness of about 0.2 to 0.3 mm.

36. The method of claim 33, wherein said  
liquid suspending medium is monoaluminum phosphate  
5 or colloidal silica.

37. A method of joining metallic or ceramic  
surfaces, which comprises the steps of providing a  
slurry having a liquid suspending medium and  
10 particulate constituents suspended in said medium  
capable of undergoing exothermic reaction by  
combustion synthesis when ignited, said  
constituents being selected from the group  
consisting of titanium dioxide, boron oxide,  
15 aluminum, titanium, boron, nickel and phosphorus;  
titanium and boron; titanium, boron, nickel and  
phosphorus; chromic oxide, carbon and aluminum; and  
mixtures thereof; applying said slurry to metallic  
or ceramic surfaces to be joined; placing said  
20 metallic or ceramic surfaces in abutting relation  
with said applied slurry therebetween; and igniting  
said slurry to cause combustion synthesis thereof  
at a temperature sufficient to fuse said metallic  
or ceramic surfaces together.

25 38. The method of claim 37, including the step  
of applying additional slurry around said metallic  
surfaces after placing said surfaces in abutting  
relation.

30 39. The method of claim 37, including the  
steps of placing a brazing alloy foil between said  
metallic surfaces, and applying additional slurry  
around said metallic surfaces after placing said  
35 surfaces in abutting relation.

26

1           40. The method of claim 37, wherein said  
liquid suspending medium is monoaluminum phosphate  
or colloidal silica.

# INTERNATIONAL SEARCH REPORT

International Application No

PCT/US 93/00661

## I. CLASSIFICATION OF SUBJECT MATTER (If several classification symbols apply, indicate all)<sup>6</sup>

According to International Patent Classification (IPC) or to both National Classification and IPC

Int.Cl. 5 B23K35/34; C04B37/00; C04B37/02; C04B41/87  
C23C24/08; C04B41/88

## II. FIELDS SEARCHED

Minimum Documentation Searched<sup>7</sup>

Classification System

Classification Symbols

Int.Cl. 5 B23K ; C04B ; C23C

Documentation Searched other than Minimum Documentation  
to the Extent that such Documents are Included in the Fields Searched<sup>8</sup>

## III. DOCUMENTS CONSIDERED TO BE RELEVANT<sup>9</sup>

Category <sup>10</sup>	Citation of Document, <sup>11</sup> with indication, where appropriate, of the relevant passages <sup>12</sup>	Relevant to Claim No. <sup>13</sup>
X	CHEMICAL ABSTRACTS, vol. 104, no. 18 Columbus, Ohio, US; abstract no. 154386h, Y. MIYAMOTO ET AL. 'Bonding of metals and ceramics' see abstract & JP,A,60 251 177 (OSAKA UNIVERSITY ET AL.)	1,4,8,9, 13,16, 18,22, 23,25, 28,32
X	--- CHEMICAL ABSTRACTS, vol. 114, no. 8 Columbus, Ohio, US; abstract no. 67830m, E. UDAGAWA 'Formation of titanium diboride sintered layer on ceramic or metal substrates' see abstract & JP,A,02 155 728 (FUJITSU LTD.) --- -/-	1,4,13, 25,28,32

<sup>10</sup> Special categories of cited documents: <sup>10</sup>

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

"&" document member of the same patent family
